The Institute for the Study of Labor (IZA) in Bonn is a local and virtual international research center and a place of communication between science, politics and business. IZA is an independent nonprofit organization supported by Deutsche Post World Net. The center is associated with the University of Bonn and offers a stimulating research environment through its international network, workshops and conferences, data service, project support, research visits and doctoral program. IZA engages in (i) original and internationally competitive research in all fields of labor economics, (ii) development of policy concepts, and (iii) dissemination of research results and concepts to the interested public.

IZA Discussion Papers often represent preliminary work and are circulated to encourage discussion. Citation of such a paper should account for its provisional character. A revised version may be available directly from the author.

## ABSTRACT

### **The Impact of Entrepreneurship Education on Entrepreneurship Competencies and Intentions: An Evaluation of the Junior Achievement Student Mini-Company Program<sup>\*</sup>**

This paper analyzes the impact of a leading entrepreneurship education program on college students' entrepreneurship competencies and intentions using an instrumental variables approach in a difference-in-differences framework. We exploit that the program was offered to students at one location of a school but not at another location of the same school. Location choice (and thereby treatment) is instrumented by the relative distance of locations to parents' place of residence. The results show that the program does not have the intended effects: the effect on students' self-assessed entrepreneurial skills is insignificant and the effect on the intention to become an entrepreneur is even significantly negative.

## 1. Introduction

Policy makers in Europe and the United States believe that more entrepreneurship is required to reach higher levels of economic growth and innovation. Indeed, empirical research supports positive links between entrepreneurial activity and economic outcomes (Van Praag and Versloot, 2007). Policy makers also believe that increased levels of entrepreneurship can be reached through education (European Commission, 2006) and especially entrepreneurship education. Therefore, such education is promoted and implemented into school curricula in many of the European member countries (European Commission, 2006) and the United States (Kuratko, 2005). A key assumption underlying these programs is that entrepreneurship skills can be taught and are not fixed personal characteristics. Indeed, it has been shown that (i) the effect of general education as measured in years of schooling on entrepreneur performance is positive (Van der Sluis et al., 2006; Van der Sluis and Van Praag, 2007), and (ii) business training is effective for the performance of people who applied for microfinance to start their own business (Karlan and Valdivia, 2006).

The dominant entrepreneurship education program in secondary schools and colleges in the US and Europe is the Junior Achievement Young Enterprise student mini-company (SMC) program. In Europe, it is effective in 40 countries and more than 2 million students have participated in the year 2005/2006. The growth rate of the number of students per annum amounts to 25% in the year 2005/2006 (Junior Achievement Young Enterprise Europe annual report, 2006).<sup>1</sup>

The SMC program involves taking responsibility as a group, for a small sized and short time business, from its setting up (usually at the beginning of the school year) to its liquidation (usually at the end of the school year). Students sell stock, elect officers, produce and market products or services; keep records and conduct shareholders' meetings. Thus, students get into contact with social and economic reality in the real business world out of the school. This is a structured project which takes 5 to 10 hours per week and is managed by a team of lecturers. Lecturers are supported by staff of the local non-profit organization "Young Enterprise". The activity takes place in class within the established curriculum, but may also be continued outside the school as a voluntary activity for the students. Each mini-company is supported by one or two advisers coming from the business world and sharing their experience with the students (EU, 2006).

---

<sup>1</sup> The idea to set up student companies was born in the twenties in the United States. Supported by, among others, Henry Ford, John Rockefeller and Walt Disney, the association 'Junior Achievement' was founded. The first student company was started up in New York. The program was exported to Europe in the sixties and was named Junior Achievement Young Enterprise.

The objective of the program is to teach students to put theory into practice and to understand what entrepreneurship is about. In this way students are assumed to gain self-confidence and motivation, become proactive, creative and learn how to work in a team (Junior Achievement Young Enterprise annual report, 2006). Despite the fact that many schools use the program, little is known about its impact on students' entrepreneurial competencies and intentions. Until now the program's successfulness has only been assessed through the appreciation of the parties involved. No solid impact evaluation study has been conducted so far (EU, 2006). The current study starts to fill this gap by evaluating the impact of a student mini-company program in a vocational college in the Netherlands in the academic year 2005/2006. To do so, we exploit the fact that this college supplies basically the same Bachelor program at two different locations, with one location offering the SMC program and the other not offering it.

Because we measure relevant outcome variables before the start of the program and after the end of it, we can apply a difference-in-differences framework. This produces unbiased estimates of the program's impact if the unobserved characteristics of students in the treated location are not systematically different from students in the untreated location insofar as these would affect the program's results, and if there are no other differences between the locations that have an impact on the outcomes related to entrepreneurship. This condition may not hold if students who are more interested in becoming an entrepreneur, are more likely to choose the location that offers the SMC program (and learn more or gain more enthusiasm as a consequence). To address this concern we apply an instrumental variables approach, where we use relative distance of the locations to the students' living place before enrolling in post-secondary education as instrument.

The main finding of this paper is that the SMC program does not have the intended effects: the effect on students' self-assessed entrepreneurial skills is insignificant and the effect on the intention to become an entrepreneur is even significantly negative.

The remainder of this paper is organized as follows. Section 2 discusses the particular program and its context. Section 3 describes the empirical approach and its identifying assumptions. Section 4 provides details about the data. Section 5 presents and discusses the empirical results. In section 6 we summarize and conclude, and offer possible explanations for the surprising findings.

## **2. Program and context**

In the Netherlands, higher education is provided by 52 vocational colleges and 13 universities. Both types of post-secondary education offer study programs at the Bachelor

level, whereas universities offer Master courses in addition.<sup>2</sup> The total number of students enrolled in vocational colleges was 357,000 in the school year 2005/2006 (205,000 in universities). Of these, 115,000 were enrolled in study programs in administration, management, economics and law (CBS, 2007) where the penetration of entrepreneurship education is highest. The SMC program is the leading entrepreneurship education program in post-secondary education in the Netherlands. Most of the student companies are set up in vocational colleges (see Figure 1), usually in the second year of the study programs in administration, management, economics and law. In the year of our study, almost 360 student mini-companies were founded in colleges, involving 3,600 students out of approximately 25,000 students. Participation in the SMC program has been growing in the Netherlands (see Figure 1).

Figure 1: Number of student mini-companies in the Netherlands per education type.

SMC programs in the Netherlands are coordinated by the Association *Jong Ondernemen*, founded in 1990 as a non-profit organization, and part of the worldwide organization Junior Achievement. The SMC programs offered are conform international standards with the features described in the Introduction. With respect to timing and student work load, in most cases, the program is run for an entire academic year on a part time basis such that students earn 10 ECTS (out of 60 per annum) by completing the program successfully. Student

<sup>2</sup> Usually, the vocational college Bachelor degree, which can be completed in three years, renders a ticket to a Master degree program of two years at the university. For comparison, after completion of a university Bachelor program this same Master degree can be obtained through a one year program. Colleges of vocational education provide more practically oriented programs and the Bachelor degree it leads to is not comparable to a university Bachelor degree.

company management teams consist of 10 students on average. In most of the schools and faculties that offer the SMC program, student participation in the program is mandatory.

Our study has taken place at the vocational college “AVANS Hogeschool”, which has three locations in the southern part of the Netherlands, in the cities Breda, Den Bosch, and Tilburg. The number of students enrolled in 2005/2006 was approximately 18,000. Hence, it is a large school with a national market share of five percent. The AVANS Hogeschool with its multiple locations is the result of a merger.<sup>3</sup> Before 2004, the Breda and Den Bosch locations had different names, though they were already managed by a single board. Actually, both locations offer many very similar study programs that have been aligned by the single board in the past years.

For four study programs in the area of administration, management, economics and law, there is actually only one important difference between the two locations: the inclusion of the SMC program. Breda has offered this on a mandatory basis in four of their study programs on a large scale already for a long time, whereas the – otherwise similar – four study programs in the Den Bosch location will only start implementing the SMC program in their curriculum in 2007/2008.<sup>4</sup>

### 3. Empirical strategy

For the evaluation of the SMC program we use an instrumental variables approach in a difference-in-differences framework (see, for instance, Leuven et al., 2007). Denote by  $y_{D=1,t=1}$  the mean value of an outcome variable after the year in which the program ran ( $t=1$ ) for those who participated in the program ( $D=1$ ), and by  $y_{D=1,t=0}$  the mean value of an outcome variable before the start of the program ( $t=0$ ) for the same group ( $D=1$ ). The difference ( $y_{D=1,t=1} - y_{D=1,t=0}$ ) is then the simple before-after estimator of the effect of the program. This estimator is, however, confounded to the extent that it also captures the effect of other changes between  $t=0$  and  $t=1$  that on the outcome of the program. To correct for that, we contrast this difference with the difference between the outcome before and after the program year of a suitable control group. As control group we use students in the location that does not offer the program ( $D=0$ ). We denote the second difference by  $(y_{D=0,t=1} - y_{D=0,t=0})$ , so that our difference-in-differences estimator equals:

$$\delta = (y_{D=1,t=1} - y_{D=1,t=0}) - (y_{D=0,t=1} - y_{D=0,t=0}).$$

<sup>3</sup> Many Dutch schools of vocational higher education were forced to merge in the past decade to establish larger scale operations.

<sup>4</sup> These programs are: business studies and accountancy, management and law, personnel studies and small business and retail management.

In practice we estimate  $\delta$  using regression analysis in which we regress individual changes in outcomes on the dummy variable for program participation. The regression equation is:

$$\Delta y_i = \alpha + \delta \cdot D_i + \varepsilon_i \quad (1)$$

Where  $\Delta y_i$  is the change in outcome for individual  $i$ ,  $D_i$  is a dummy variable equal to 1 if respondent  $i$  attended the location that offered the SMC-program and 0 otherwise, and  $\varepsilon_i$  is an error term.<sup>5</sup> We will also present estimates of equation (1) including a set of student background characteristics ( $X$ ), such as gender and age.

Students' location choices are potentially endogenous; those who are more interested in becoming an entrepreneur, may have chosen the location that offers the SMC program. The difference-in-differences framework addresses this problem to the extent that differences between the groups of students shows up in the baseline levels of entrepreneurial competencies and intentions. It does not, however, accommodate differences in changes in these outcome variables due to unobserved differences between the students of both locations. Therefore, this might invalidate the parallel trend assumption; the before-after difference for the untreated students measures what would have been the before-after difference for the treated students in the absence of the SMC-program. To address the concern that this assumption is not valid for instance because students who expect to gain the most from the SMC program attend the location that offers this program, we apply an instrumental variables approach. As instrument for location choice we use the relative distance of the locations to the students' living place before enrolling in post-secondary education  $Z$  (mostly their parents' place of residence). The identifying assumption is then that (conditional on covariates) this relative distance is unrelated to the error term in the change in outcome equation:  $E(Z_i \cdot \varepsilon_i | X_i) = 0$ .

The parallel trend assumption also implies that in the absence of the program treated students would have been exposed to the same alternative treatment as the untreated students. However, it is unlikely (and would be undesirable) that untreated students spent the time idly that the treatment group spent on the program. Instead, they may have attended courses that contributed to their entrepreneurial competencies and intentions. To assess this, the Appendix provides more details about the curricula in the second year in the treatment and controls locations per program. Comparison of these programs shows that courses that were taught in the control programs are not particularly directed to the development of entrepreneurial

---

<sup>5</sup> For all the results we report heteroskedasticity robust standard errors.

competencies or to the motivation to become an entrepreneur. Based on the parallel trend assumption we assume that treated students would have done the same if the program was not offered to them. Thus, we estimate the net effect of the SMC program, that is: the effect over and above what is accomplished by programs that are locally designed and organized by the schools themselves and that are not particularly directed towards developing entrepreneurship.<sup>6</sup>

The main limitation of our research design is that we only compare students from two different locations of the same school. Our findings are therefore only informative about the successfulness of the SMC program at that school. Whether the same program is more or less successful when implemented elsewhere remains an open question.

#### **4. Data**

This section starts with describing in some detail how entrepreneurial competencies and intentions have been measured. After that it describes how the data were collected and presents descriptive statistics.

##### *Measurement of entrepreneurial competencies and intentions*

Based on many studies of the determinants of successful entrepreneurship, primarily from psychology and business studies, the so-called Escan has been developed (see Driessen and Zwart, 1999; Driessen, 2005). The Escan is a validated self-assessment test based on 114 items (questions and statements) posed to individuals. This is the test we have used to measure students' entrepreneurial competencies. The Escan is widely used in the Netherlands to determine people's entrepreneurial competencies. It is sold through internet to individuals and is used by various companies and institutes, such as the Dutch Chambers of Commerce. For instance, it is a regular test used by a major bank (the Rabo bank) in their assessment of loan granting to starting entrepreneurs. Moreover, it is a standard part of the Dutch SMC program: students use their assessed strengths and weaknesses to determine which competencies should be further developed during the program. The test results have been shown to correlate significantly with objective measures of entrepreneurial performance in terms of survival, profits, income and sales (see Driessen and Zwart, 1999).

---

<sup>6</sup> Given the local design of non-SMC curricula, it is doubtful whether a local alternative curriculum in the treatment location would have been exactly the same. We know, however, that when the control location implements the SMC curriculum, it will be similar to the curriculum in the treatment location. Our impact estimates can therefore be interpreted as the average treatment effect on the untreated.

The majority (89) of the 114 items are statements and respondents answer on a seven-point scale to what extent they agree with the statement.<sup>7</sup> The statements load into ten factors (with Cronbach alpha's ranging from 0.69 to 0.85) that the entrepreneurship literature has shown to be the most important determinants of successful entrepreneurship, see Table 1.

Table 1: Entrepreneur traits and skills

|                        | <i>Number of items</i> | <i>Cronbach's <math>\alpha</math></i> | <i>Correlation with entrepreneurial intentions</i> |                     |

Note: Columns (1) and (2) based on Driessen and Zwart (1999) Table 3. \*\*/\*\* indicates significance at the 5%/1%-level.

The first competency is *need for achievement*. Successful entrepreneurs score high on need for achievement by striving for performance adequately and competing, if necessary. They build their company with their professional goals in mind. They set high target levels and put in much effort to reach them. *Need for autonomy* is often the (sub)conscious reason for choosing entrepreneurship. Successful entrepreneurs score high on this competency that reflects independent decision making, the ability to resolve their problems and to bring activities to a successful end on their own. The *need for power* is the need to have control over others, to influence their behavior. Successful entrepreneurs score high on this competency indicating that they know what they want and how to influence others to achieve

<sup>7</sup> Examples of statements are: "I adapt my plans upon changes in circumstances", "I am extremely orientated towards performance", "I prefer other people to take decisions for me", "When I start something new, I know I will succeed", "I have much self-confidence" and "I always persevere until I have reached my target".

their own goals. *Social orientation* reflects the understanding (of successful entrepreneurs) that connections with others are required to realize their ideas. They make these connections easily and are driven by professional considerations in their social activities. They set their social needs aside and focus on their business. *Self efficacy* reflects the belief in one's own ability, i.e., self-confidence. Successful entrepreneurs are usually convinced that they can bring every activity to a successful end. Also, they feel that they can control their own success, which does not depend on others. Successful entrepreneurs have a high degree of *endurance*. It involves the ability to continue willfully, in spite of setbacks or objections. *Risk taking propensity* in the Escan reflects both the ability to deal with uncertainty and the willingness of risking to take a loss. These are important competencies for successful entrepreneurs.

*Market awareness* is the ability to sympathize with the needs of (potential) clients and to link these to one's own business. Successful entrepreneurs appeal to the specific needs of a clearly defined target group of customers and have the ability to anticipate changes in the market based on their awareness of the needs and wants of customers and the (planned) activities of competitors. *Creativity* is the ability to adopt views from different perspectives and to see and try new possibilities based on open observations of (changes in) the environment. Moreover, creativity reflects the capability to turn problems into new opportunities. It is an important ingredient for successful entrepreneurship. *Flexibility*, finally, is based on a measure of the ability to adapt. Successful entrepreneurs react to changes they observe in their environment, such as new needs of clients or new competitors in their market.

A distinction is made between seven traits and three skills, see Table 1. In general, traits do not change over time and are therefore assumed not to be affected by the programs. However, skills can be learned and improved by program participation (Driessen 2005) and are thus more likely to change in the observed period. Because the Escan is a test based on the subject's self-assessment, it is also possible that trait measures change over time. Student scores on each of the ten factors are administered on a scale from 1 to 10. We have also aggregated these scores into average scores for 'entrepreneur traits' and 'entrepreneur skills'. The first is the average of the first seven scores, the latter the average of the last three scores.

A short questionnaire was added to the original Escan items to obtain information on students' backgrounds and the self-perceived likelihood of becoming an entrepreneur within the next fifteen years (based on the statement "I expect to start up a new firm or to take over an existing firm within the next fifteen years" and answers on a seven-point scale ranging from "completely agree" to "completely disagree"). The latter is used as a measure of entrepreneurial intentions. The last two columns in Table 1 report the pairwise correlations between each of the entrepreneurial competencies measured by the Escan and the response to

the question about entrepreneurial intentions. Column (3) does this for the values measured at baseline ( $t=0$ ), column (4) is based on the values measured in the follow-up survey ( $t=1$ ). With one (baseline) or two (follow-up) exceptions, all these correlations are significantly positive. This reinforces the claim that the competencies measured are associated with entrepreneurship (though not necessarily with successful entrepreneurship).

Besides measuring students' entrepreneurial intentions, the survey served to obtain background information about the students in terms of their gender, nationality, age, secondary education, parental education levels and parental entrepreneurial activity. Moreover, we gathered the students' postal codes just prior to starting their post-secondary education through the survey. Based on these, we calculate the distance to both the treatment and the control location and use the difference between the two as instrumental variable for actual location choice.

### *Sample*

The survey and Escan were offered prior to the start of the program in September 2005 to a total number of 562 students in four study programs at the treatment (Breda) and control (Den Bosch) locations. The lecturers collaborated in obtaining responses by emphasizing the importance of filling out the questionnaires to their students. Moreover, the management of the school and the regional coordinator of the Association Jong Ondernemen (the latter only for the treatment population) were involved in organizing sessions where students could take the computer test at their school in our presence. The survey and Escan were emailed to students who did not attend these sessions for whatever reason. Tests were not anonymous such that we could merge the results of this pre-measurement with the post-measurement scores on an individual basis. Of the 219 students in the treatment group and the 343 students in the control group, 189 (86%) and 220 (64%) valid<sup>8</sup> surveys were administered at the beginning of the academic year. For students in the treatment group, filling out the Escan is a regular part of the program.

In the period July to September of 2006 the 409 students in the sample were requested to fill out the survey and Escan again.<sup>9</sup> This time we experienced difficulties in reaching the students, because the end of the program was followed immediately by a prolonged period of summer vacation. We used the help of lecturers, sent emails to the students and placed follow-up phone calls, when necessary. We thus managed to obtain 104 valid post measurement observations in the treatment group and 146 in the control group. The net

---

<sup>8</sup> Sixteen surveys were invalid due to missing values or repeatedly filling out identical answers (for at least 20 consecutive items).

<sup>9</sup> The items pertaining to time invariant background characteristics were omitted.

response rates over two waves are remarkably similar for treatment and control locations; 47% versus 43%.

All analyses are based on these 250 observations. Unfortunately, there is no way in which we can ascertain that the initial non-response is random. However, we analyze the non-response or attrition bias at the post measurement phase, see below.

*Pre-treatment differences between treatment and control groups*

The validity of the difference-in-differences approach hinges on the comparability of the treatment and control groups. It is therefore important to examine differences between these groups in terms of pre-treatment variables.

The first two columns of Table 2 show to what extent the pre-treatment outcomes and background variables differ between the treatment and the control group. The treatment and control groups are not significantly different from each other before the program started for most of the variables. Exceptions are the score on the skill ‘market awareness’ which is higher in the control than in the treatment group, the age distribution in the sense that there is a significantly higher percentage of students older than 21 in the control group, and finally, the percentage of students in the program business studies and accountancy.<sup>10</sup> Differences between the treatment and the control group thus appear to be negligible. Nevertheless, we do not exclude the possibility that the treatment and control groups differ in terms of unobservables that might affect the measured outcomes. Therefore, we shall instrument the observed location choice.

Table 2: Pre-treatment differences between the treatment and control group

|                                 | <i>Final sample</i> |         | <i>Full pre-attrition sample</i> |         |

The first two columns report mean values for the sample that is used in the analysis at baseline. The last two columns show the same statistics for the entire, including that are absent post-treatment due to attrition. If both numbers are underlined they are significantly different at the 5% level.

#### *Attrition bias*

The last two columns of Table 2 show to what extent the pre-treatment outcomes and background variables differ between the treatment and the control group at  $t=0$  if all available observations are included, also the ones for which no post-measurement values are available due to attrition.

A comparison of the first and the second sets of two columns shows that attrition is unlikely to bias the results. All differences between the treatment and the control group in the used sample are very similar for the extended sample as shown in the last two columns. There are three differences between the treatment and the control group that are slightly different across the used and the extended sample. First, for market awareness, the difference between the treatment and the control group is insignificant in the extended sample whereas it is significant in the used sample. Nevertheless, the differences are almost equal and qualitatively the same. The second difference pertains to the age distribution. In both samples, the percentage of students younger than 19 is higher in the treatment group than in the control group. The difference is significant in the extended but not in the used sample. However, the percentages are very similar (28% versus 20% in the used sample and 30% versus 21% in the extended sample). The same holds for the older age brackets. The differences are similar, but they are significant in one sample and not in the other. The third difference relates to the distribution of students over faculties. Again, the differences (in the differences) between the two samples are negligible.

## **5. Results**

### *First stage results*

For our estimation of treatment effects we use relative distance of the locations to the students' living place before enrolling in post-secondary education as an instrumental variable for observed location. Breda and Den Bosch are two of the main cities in the Dutch province of Noord-Brabant. The distance between the two cities is around 40 kilometers, with Breda being located more to the west.

One requirement for a variable to be a suitable instrument is that it has a significant impact on the endogenous variable. Table 3 shows the results from first stage regressions. The specification in the first column includes no other covariates, whereas the specification in the second column includes controls for background characteristics and dummy variables for study programs. In both specifications relative distance is highly significant as indicated by the F-values for the test that this variable could be deleted. The point estimate and its standard error hardly change when controls are included. None of the coefficients of the covariates included in the second specification is significantly different from zero. This establishes that relative distance is the key determinant of location choice and thus of assignment to treatment or control group.

Table 3: First stage regressions

|                           | (1)                    | (2)                    |
|---------------------------|------------------------|------------------------|
| Relative distance (in km) | -0.0118***<br>(0.0004) | -0.0115***<br>(0.0005) |
| Control variables         | No                     | Yes                    |
| F-value for instrument    | 771.05***              | 583.72***              |
| N                         | 250                    | 250                    |

Note: Dependent variable is location choice (1=Breda/treatment; 0=Den Bosch/control). Robust standard errors in parentheses. \*\*\* indicates significance at the 1%-level.

For an instrument to be valid, it should have no direct impact on the outcomes of interest. This identifying assumption can not be tested. We can, however, regress baseline values of the various outcomes on the instrument. Table 4 reports the results, in column (1) for a specification without controls and in column (2) for a specification with controls. Only for one of the 13 (aggregated) outcome variables we find a significant positive coefficient for the instrument; this is for market awareness, with the positive sign suggesting that students living closer to the control location have higher levels of market awareness (as was also shown in Table 2). The impact is, however, small in absolute size. The maximum difference in distance is 40 kilometers, so that the maximum difference in market awareness related to differences in distance equals 0.24. Recall that the outcome variables are measured on a scale from 1-10.

Table 4: Effect of distance (instrument) on baseline values of outcome variables

|                                | (1)             | (2)              |

Note: \*\*/\*\* indicates significance at the 5%/1%-level. Number of observations equals 250.

### *Treatment effects*

Table 5 shows the main results of this paper. Column (1) gives the mean values of the outcome variables for the treatment group at baseline, and column (2) their outcomes after the intervention. Column (3) contains the difference between these two columns. Columns (4) to (6) give the same information for the students in the control group. The differences of these differences are reported in column (7). These estimates are obtained by estimating equation (1) without covariates. The estimates in column (8) come from a regression including covariates. Columns (9) and (10) show the estimation results when using the IV-approach.

Hausman tests for the endogeneity of treatment reveals that treatment is only endogenous in the case of the composite variable “Entrepreneurial skills”.<sup>11</sup> Apparently, students with the ability and willingness to develop these skills are more likely to be found in the control than the treatment location. For efficiency reasons we base our inferences on the results in columns (7) and (8), except for “Entrepreneurial skills”, for which the IV-estimates are preferred.

<sup>11</sup> This result is based on Hausman tests for which the predicted probability of treatment is added to the OLS regressions. A significant coefficient on this variable indicates that treatment is endogenous.

Note: All effect estimates in the various rows of columns 7-10 come from separate regressions. Robust standard errors in parentheses. \*/\*\*/\*\* indicates significance at the 10%/5%/1% level.

According to the preferred estimates, the SMC program has a significantly negative impact on entrepreneurial intentions, and a zero impact on entrepreneurial skills (and traits). The result is very surprising given the program's objective to develop entrepreneurial skills and affect entrepreneurial intentions of the students exposed to it positively.

The finding that entrepreneurial skills do not increase more for treated than for untreated students is indicative of an ineffective program, at least as it is executed at the school of our analysis and relative to the programs that are offered in the control location. However, the finding that the average effect of the program on students' intentions to become entrepreneurs is negative does not necessarily indicate that the program is ineffective. In interviews with lecturers and business coaches involved in the program, it was suggested that the SMC program makes students' expectations about entrepreneurship more realistic. Even with a negative average effect of the SMC program on entrepreneurial intentions, the benefit of the program could be that students with low levels of entrepreneurial competencies become less enthusiastic about entrepreneurship, whereas students with high levels of entrepreneurial competencies become more enthusiastic. We tested for such heterogeneous treatment effects on entrepreneurial intentions by including interactions between the treatment indicator and students' levels of entrepreneurial competencies before the start of the program. This reveals that the effect of treatment is not distinct for students who are potentially successful entrepreneurs and students with less entrepreneurial potential. Hence, the negative effect of the SMC program on entrepreneurial intentions cannot be assessed as beneficial.

## **6. Conclusion**

This paper analyzes the impact of the leading entrepreneurship education program on entrepreneurial competencies and intentions using an instrumental variables approach in a difference-in-differences framework. We exploit that the program was offered to students at one location of a school but not to students at another location of the same school. We instrument treatment by relative distance of parents' place of residence to the locations.

The results show that the program does not have the intended effect: The effects on students' self-assessed entrepreneurial skills (and traits) are not significantly different from zero and the point estimates are even negative. The effect on entrepreneurial intentions is significantly negative. This result stands in sharp contrast to earlier positive outcomes of assessments based on the appreciation of the parties involved.

The results can possibly be related to the fact that students have obtained more realistic perspectives both on themselves as well as on what it takes to be an entrepreneur. A more realistic self-perception may have caused the (insignificant) decreases in the traits measures: given that traits themselves do not change over time, the insignificantly lower

values of the traits scores after treatment must be due to changes in self-perception. In the same vein, changes in self-perception might have caused the slight decreases in the entrepreneurial skill levels of program participants as these are of the same order of magnitude as the changes in traits scores. However, the fact that these changes in self-perception are reflected in lower skill levels and are apparently not (at least) compensated by higher actual levels of these skills is worrisome, and indicative of the ineffectiveness of the program at the school of our study.

The negative impact of the program on the intention to become an entrepreneur can be due to a more realistic view of what is needed to start an own business as was suggested in interviews that were held with lecturers and coaches. More indirectly, participants might have lost their (over-)optimism (as reflected in their lower self-perception) and this may have caused a lower interest in entrepreneurship.<sup>12</sup> Alternatively, the program participants may simply have disliked the program. Various factors may have contributed to that: participation is compulsory, the time and effort input demanded from participants is high relative to the credit points they earn, and the number of students per group is large (ten on average) which may hamper active involvement and may have caused some participants to free-ride.

The contribution of our study is that it is the first solid impact evaluation of the SMC program. However, the internal validity comes at a cost: the lack of external validity since we analyze the program in only one school. We do not base any policy implications on the results of just one study. The implication of our study is that more impact evaluations along the lines of our study should be conducted in collaboration with the schools in order to ensure a random allocation of students across treatment and control groups. Moreover, studies that assess the effectiveness of variants of the program in terms of aspects such as the entrepreneur team's size, the duration of the program, mandatory versus voluntary participation in the program and the number of student credit points earned would be instructive.

## Appendix: Detailed comparison of curricula of treatment and control study programs

This appendix describes the curricula of the four treatment study programs and control study programs. It also discusses links between the curriculum and the student company in the treatment programs.

Program Business Economics & Accountancy

Location *Treatment*

General Subjects are provided with courses that are part of the following fields

Curriculum: Business Economics  
Tax law  
General economics  
Finance  
Financial Accounting

Other There are behavioral competences linked to the Student Company program. These competences are evaluated for each student. During class and in the students' company program, the student has to practice the competences and address shortcomings. The competences are:

Oral and written communication

Presentation

Integrity

Customer mindedness

Program Business Economics & Accountancy

Location *Control*

General Students are provided with a combination of theory and practice assignments  
Central point of focus are competences.

Curriculum: Business plan  
Tax Law  
General economics  
Finance  
Marketing  
Ethics  
Entrepreneurial law

Other N/A

Program Management & Law

Location *Treatment*

General Subjects are provided in four categories: The company's beginning, the company's environment, the growing company and the controlled company. The students receive quite some freedom and a high degree of autonomy is required.

Curriculum: The subjects provided in the Company's Beginning are:  
Marketing / Communication  
Fiscal/ juridical

Business Economics / Finance

The subjects provided in the Company's Environment are:

The roles of the (inter)national government

Sustainable Entrepreneurship

Analysis of mission, strategy and targets

English

The subjects provided in the Growing Company are:

Juridical

Finance

(Human Resource) Management

The subjects provided in the Controlled Company are:

Planning & Control

Information systems

Information gathering

Qualitative and quantitative methods

Written communication

Other

There are eight behavioral competences linked to the Student Company program.

These competences are evaluated for each student and during the classes

and the student company program, the student has to practice the competences

and address shortcomings. The competences are:

Planning & Organizing

Controllability

Entrepreneurship

Oral Communication and Presentation

Cooperation

Adaptiveness

Initiative

Result mindedness

Program

Management & Law

Location

*Control*

General

Subjects are provided in clearly defined courses

Curriculum:

Marketing

Communication

Intellectual Property

Management Accounting

Information systems

Market Mindedness

Purchase

Contract law

Suppliers' choice

Logistics

English

Administrative organization

Risk analysis (labor)

Activity Based Costing

Quality control

Production Logistics
